Arithmetic conditions for the existence of G_2 -instantons over twisted connected sums

Thomas Walpuski

2019-10-08

Abstract

Extending earlier work in [Wal16] this article introduces an arithmetic condition which guarantees the existence of G_2 -instantons over twisted connected sums. By brute-force search a significant number of solutions of this condition can be found. This yields many new examples of G_2 -instantons and, in particular, the first examples of irreducible, unobstructed G_2 -instantons on **P**U(r)-bundles for $r \neq 2$.

1 Introduction

The first few examples examples of irreducible unobstructed G_2 -instantons on SO(3)-bundles where constructed in [Wal13]. These examples are defined over G_2 -manifolds constructed by Joyce [Joy96a; Joy96b] by resolving flat G_2 -orbifolds. By far the most fruitful method for constructing G_2 -manifolds to date is the twisted connected sum construction [Kov03; KL11; CHNP13; CHNP15]. While there is a gluing theorem to produce G_2 -instantons over twisted connected sums [SW15], so far there are only two examples of G_2 -instantons constructed using this theorem in the literature [Wal16; MNS17]. This article slightly extends the work in [Wal16] and shows that the ideas developed there can, in fact, be used to produce a rather large number of G_2 -instantons.

After reviewing (a special case of) the twisted connected sum construction in Section 2, an arithmetic condition for the existence of G_2 -instantons is given and proved in Section 3. Solutions to this arithmetic condition can be found by a simple brute-force search algorithm outlined in Section 4. A concrete implementation in SAGE/PYTHON of this algorithm (with a quite restricted search scope) finds 299 solutions of the aforementioned arithmetic condition. This yields, in particular, the first examples of irreducible, unobstructed G_2 -instantons on PU(r)-bundles with $r \neq 2$. Further statistics regarding these can be found in Section 5.

2 Twisted connected sums from Fano 3-folds

2.1 The twisted connected sum construction

Definition 2.1 (Corti, Haskins, Nordström, and Pacini [CHNP13, Definition 5.1]). A **building block** is a smooth projective 3–fold *Z* together with a projective morphism $\pi : Z \to \mathbf{P}^1$ such that the following hold:

- 1. The anticanonical class $-K_Z \in H^2(Z)$ is primitive.
- 2. $\Sigma := \pi^*(\infty)$ is a smooth *K*3 surface and $\Sigma \sim -K_Z$.

Definition 2.2. A framing of a building block (Z, Σ) consists of a hyperkähler structure $\boldsymbol{\omega} = (\omega_I, \omega_J, \omega_K)$ on Σ such that $\omega_J + i\omega_K$ is of type (2, 0) as well as a Kähler class on Z whose restriction to Σ is $[\omega_I]$.

Given a framed building block (Z, Σ, ω) , using the work of Haskins, Hein, and Nordström [HHN15], we can make $V := Z \setminus \Sigma$ into an asymptotically cylindrical (ACyl) Calabi–Yau 3–fold with asymptotic cross-section $S^1 \times \Sigma$; hence, $Y := S^1 \times V$ is an ACyl G_2 -manifold with asymptotic cross-section $T^2 \times \Sigma$.

Definition 2.3. A matching of pair of framed building blocks $(Z_{\pm}, \pi_{\pm}, \omega_{\pm})$ is a hyperkähler rotation $\mathfrak{r}: \Sigma_{+} \to \Sigma_{-}$, i.e., a diffeomorphism such that

$$\mathfrak{r}^*\omega_{I,-} = \omega_{J,+}, \quad \mathfrak{r}^*\omega_{J,-} = \omega_{I,+} \quad \text{and} \quad \mathfrak{r}^*\omega_{K,-} = -\omega_{K,+}.$$

Given a matched pair of framed building blocks $(Z_{\pm}, \pi_{\pm}, \omega_{\pm}; \mathfrak{r})$, the twisted connected sum construction produces a simply-connected compact 7–manifold Y together with a family of torsion-free G_2 -structures { $\phi_T : T \gg 1$ } by gluing truncations of Y_{\pm} along their boundaries via interchanging the circle factors and \mathfrak{r} . Denote by $\Upsilon : H^{\text{ev}}(Z_+) \times_{H^{\text{ev}}(\Sigma_+)} H^{\text{ev}}(Z_-) \to H^{\text{ev}}(Y)$ the splicing map defined in [CHNP₁₅, Definition 4.15].

2.2 Building blocks from Fano 3-folds

Proposition 2.4 ([Kovo3, Proposition 6.42; CHNP15, Proposition 3.17]). Let W be a Fano 3–fold and let $|\Sigma_0, \Sigma_\infty| \in |-K_W|$ be anti-canonical pencil such that Σ_∞ is a smooth K3 surface and the base locus C is a smooth curve. Set

$$Z := \operatorname{Bl}_C W$$

and denote by $\pi: Z \to \mathbf{P}^1$ the map induced by the pencil $|\Sigma_0, \Sigma_{\infty}|$. In this situation the following hold:

- 1. $\pi: Z \rightarrow \mathbf{P}^1$ is a building block and
- 2. the inclusion $\Sigma_{\infty} \subset W$ induces an isomorphism $\pi^*(\infty) \cong \Sigma_{\infty}$.

Definition 2.5. A building block arising from Proposition 2.4 is said to be of Fano type.

Remark 2.6. Let *W* be a Fano 3–fold whose anticanonical bundle $-K_W$ is very ample. By Bertini's theorem, the adjunction formula, and the Lefschetz hyperplane theorem a general anti-canonical divisor is a smooth K₃ surface Σ_{∞} . A further application of Bertini's theorem shows that having chosen Σ_{∞} one can always find Σ_0 such that the base locus of $|\Sigma_0, \Sigma_{\infty}|$ is smooth. Moreover, for a general Σ_0 the morphism π has only finitely many singular fibres and the singular fibres have only ordinary double point singularities; see [Voio7, Corollary 2.10].

2.3 Matching Fano 3-folds

Definition 2.7. The **Picard lattice** of a smooth complex 3-fold W is Pic(W) equipped with the quadratic form

$$x \otimes y \mapsto x \cdot y \cdot (-K_W)$$

Definition 2.8. Let *N* be a lattice. An *N*-marking of a Fano 3-fold *W* is an isometry $h: N \rightarrow \text{Pic}(W)$. A pair of *N*-marked Fano 3-folds (W_1, h_1) and (W_2, h_2) are **deformation equivalent** if there is a proper holomorphic submersion $\pi: X \rightarrow \Delta$ from a complex manifold to the unit disc in C such that W_1 and W_2 both occur as fibers of π and parallel transport induces the isometry $h_1^{-1}h_2$. An *N*-marked deformation type of Fano 3-folds is a maximal set \mathcal{W} of *N*-marked Fano 3-folds such that every pair of elements of \mathcal{W} are deformation equivalent.

Definition 2.9. Let N_{\pm} and N_0 be non-degenerate lattices and let $i_{\pm} \colon N_0 \hookrightarrow N_{\pm}$ be embeddings. An **orthogonal pushout** of i_+ and i_- is a lattice N together with embeddings $j_{\pm} \colon N_{\pm} \hookrightarrow N$ such that the diagram

is commutative,

$$j_{\pm}(N_{\pm}) \cap j_{-}(N_{-}) = i_{\pm}j_{\pm}(N_{0}), \quad N = j_{\pm}(N_{\pm}) + j_{-}(N_{-}), \text{ and } j_{\pm}(N_{\pm})^{\perp} \subset j_{\mp}(N_{\mp}).$$

Situation 2.10. Let $r_{\pm}, r_0 \in \mathbb{N}$ with $r_+ + r_- - r_0 \leq 11$. Let N_{\pm} be lattices of signature $(1, r_{\pm} - 1)$, let N_0 be a lattice of signature $(0, r_0)$, let $i_{\pm} \colon N_0 \hookrightarrow N_{\pm}$ be primitive embeddings, and let (N, j_+, j_-) be an orthogonal pushout of i_+ and i_- . Let $\operatorname{Amp}_{\pm} \subset N_{\pm} \otimes_{\mathbb{Z}} \mathbb{R}$ be open cones. Let \mathcal{W}_{\pm} be N_{\pm} -marked deformation types of Fano 3-folds such that for every $(W_{\pm}, h_{\pm}) \in \mathcal{W}$:

- 1. $-K_{W_{\pm}}$ is very ample,
- 2. $h_{\pm}^{-1}(Amp_{\pm})$ is contained in the ample cone of W_{\pm} , and
- 3. Amp_± \cap $(i_{\pm}(N_0) \otimes_{\mathbb{Z}} \mathbb{R})^{\perp} \neq \emptyset$.

Proposition 2.11. Assume Situation 2.10. For every $H_{\pm} \in \operatorname{Amp}_{\pm} \cap (i_{\pm}(N_0) \otimes_{\mathbb{Z}} \mathbb{R})^{\perp}$ and $\varepsilon > 0$, there exist $(W_{\pm}, h_{\pm}) \in \mathcal{W}_{\pm}$, smooth K3 surfaces $\Sigma_{\pm} \in |-K_{W_{\pm}}|$, hyperkähler structures $\omega^{\pm} = (\omega_I^{\pm}, \omega_J^{\pm}, \omega_K^{\pm})$ on Σ_{\pm} , and a hyperkähler rotation $\mathfrak{r}: (\Sigma_+, \omega_+) \to (\Sigma_-, \omega_-)$ such that:

- 1. the restriction maps res_{\pm} : $\operatorname{Pic}(W_{\pm}) \to \operatorname{Pic}(\Sigma_{\pm})$ are isomorphisms,
- 2. the diagram

$$N_{0} \xrightarrow{h_{+}} \operatorname{Pic}(W_{+}) \xrightarrow{\operatorname{res}_{+}} \operatorname{Pic}(\Sigma_{+})$$

$$\downarrow^{r_{*}}$$

$$h_{+} \xrightarrow{\operatorname{Pic}(W_{-})} \xrightarrow{\operatorname{res}_{-}} \operatorname{Pic}(\Sigma_{-})$$

is commutative, and

3. the distance between $\mathbf{Rh}_{\pm}(H_{\pm})$ and $\mathbf{R}[\omega_{I}^{\pm}]$ in $\mathbf{PH}^{2}(\Sigma_{\pm}, \mathbf{R})$ is at most ε .

Proof. Therefore, [CHNP15, Proposition 6.18] applies. By [Moĭ67, Theorem 7.5] for very general $\Sigma_{\pm} \in -K_{W_{\pm}}$ the conclusion (1) holds. By [Nik79, Theorem 1.12.4 and Corollary 1.12.3], *N* embeds primitively into the K3 lattice. Therefore, the framing and hyperkähler rotation can thus be obtained from [CHNP15, Proposition 6.18] and (2) holds by construction. The observation that in this construction one may assume (3) is due to [MNS17, Proposition 2.6].

Choosing further anticanonical divisors as in Proposition 2.4 one obtains a matched pair of framed building blocks $(Z_{\pm}, \pi_{\pm}, \omega_{\pm}; \mathfrak{r})$ which can be feed into the twisted connected sum construction.

3 An existence theorem for *G*₂-instantons

Theorem 3.1. Assume Situation 2.10. Let

$$H_{\pm} \in \operatorname{Amp}_{+} \cap i_{\pm}(N_{0})^{\perp}$$
 and $v = (r, B, s) \in \{2, 3, \ldots\} \times N_{0} \times \mathbb{Z}$

such that the following hold:

- 1. $B^2 = 2(rs 1)$,
- 2. the r and the divisibility of B are coprime, r and s are coprime; and
- *3.* for every non-zero $x \in N_{\pm}$ perpendicular to H_{\pm}

$$x^2 < -\frac{1}{2}r^2(r^2 - 1).$$

In this situation there is a matched pair of framed building blocks $(Z_{\pm}, \pi_{\pm}, \omega_{\pm}; \mathfrak{r})$ obtained from Proposition 2.11 and for $T \gg 1$ the corresponding twisted connected sum carries an irreducible and unobstructed G_2 -instanton on a non-trivial PU(r)-bundle.

3.1 A gluing theorem for G_2 -instantons over twisted connected sums

Theorem 3.2 (Sá Earp and Walpuski [SW15, Theorem 1.3 and Remark 1.7]). Let $(Z_{\pm}, \pi_{\pm}, \omega_{\pm}; \mathfrak{r})$ be a matched pair of framed building blocks. Set $\Sigma_{\pm} := \pi_{\pm}^*(\infty)$. Denote by Y the compact 7-manifold and by $\{\phi_T : T \gg 1\}$ the family of torsion-free G_2 -structures obtained from the twisted connected sum construction. Let $\mathscr{C}_{\pm} \to Z_{\pm}$ be a pair of rank r holomorphic vector bundles such that the following hold:

- 1. $c_1(\mathscr{C}_+|_{\Sigma_+}) = \mathfrak{r}^*c_1(\mathscr{C}_-|_{\Sigma_-})$ and $c_2(\mathscr{C}_+|_{\Sigma_+}) = \mathfrak{r}^*c_2(\mathscr{C}_-|_{\Sigma_-})$.
- 2. $\mathscr{C}_{\pm}|_{\Sigma_{\pm}}$ is μ -stable with respect to $\omega_{I,\pm}$ and rigid, i.e.,

 $H^1(\Sigma_{\pm}, \mathscr{E}\mathrm{nd}_0(\mathscr{E}_{\pm}|_{\Sigma_{\pm}})) = 0.$

3. \mathscr{E}_{\pm} is infinitesimally rigid:

 $H^1(Z_{\pm}, \mathscr{E}\mathrm{nd}_0(\mathscr{E}_{\pm})) = 0.$

In this situation exists a U(r)-bundle E over Y with

 $c_1(E) = \Upsilon(c_1(\mathscr{C}_+), c_1(\mathscr{C}_-))$ and $c_2(E) = \Upsilon(c_2(\mathscr{C}_+), c_2(\mathscr{C}_-)).$

and a family of connections $\{A_T : T \gg 1\}$ on the associated PU(r)-bundle with A_T being an irreducible unobstructed G_2 -instanton over (Y, ϕ_T) .

3.2 Relative moduli spaces of sheaves

Definition 3.3. Let $\pi \colon Z \to \mathbf{P}^1$ be a building block. Define $\mathbf{M} \colon \mathbf{Sch}_{\mathbf{P}^1}^{\mathrm{op}} \to \mathbf{Set}$, the **relative moduli functor** of coherent sheaves on *Z*, as follows:

- Let *S* be \mathbb{P}^1 -scheme. Two such sheaves \mathscr{E} and \mathscr{F} over $Z \times_{\mathbb{P}^1} S$ are consider to be equivalent if there exists a line bundle over *S* such that \mathscr{E} and $\mathscr{F} \otimes \mathscr{L}$ are isomorphic. We define $\mathbb{M}(S)$ the be the set of equivalence classes of *S*-flat coherent sheaves on $Z \times_{\mathbb{P}^1} S$.
- Given a morphism $f: S \to T$ of \mathbb{P}^1 -schemes, set

$$\mathbf{M}(f)[\mathscr{C}] \coloneqq [f^*\mathscr{C}].$$

Definition 3.4. Let $\pi: Z \to \mathbf{P}^1$ be a building block. Let \bullet denote an open condition on coherent sheaves on the fibers of π . Denote by \mathbf{M}_{\bullet} the open subfunctor of \mathbf{M} defined by

 $\mathbf{M}_{\bigstar}(S) \coloneqq \{ [\mathscr{C}] \in \mathbf{M}(S) : \text{for every } b \in S \text{ the fiber } \mathscr{C} \otimes_{\mathscr{O}_S} \mathbf{C}(b) \text{ satisfies } \clubsuit \}.$

We say that M_{\bullet} is **representable** if there exists a P^1 -scheme M_{\bullet} together with a natural isomorphism

$$\phi$$
: Hom_{P1}(\cdot, M_{\bullet}) \cong M_•(\cdot).

In this case we call M_{\bullet} the relative moduli space of coherent sheaves on Z satisfying \bullet . A universal sheaf over $Z \times_{P^1} M_{\bullet}$ is a sheaf in the equivalence class $\phi(\operatorname{id}_{M_{\bullet}}) \in \mathbf{M}_{\bullet}(M_{\bullet})$.

Remark 3.5. Typical examples of representable subfunctors of **M** arise by imposing stability conditions [Mar78; Mar77; Sim94]. However, these are not the only examples; see, e.g., Drézet [Dréo8].

Suppose that $M = M_{\bullet}$ is a relative moduli space of coherent sheaves on Z with universal sheaf \mathscr{U} . Being a \mathbf{P}^1 -scheme, M comes with a morphism $\varpi \colon M \to \mathbf{P}^1$. A morphism $\mathbf{P}^1 \to M$ of \mathbf{P}^1 -schemes is simply a morphism $s \colon \mathbf{P}^1 \to M$ with $\varpi \circ s = \mathrm{id}_{\mathbf{P}^1}$, that is, a section of ϖ . By construction any such section yields a coherent sheaf $(\mathrm{id}_Z \times_{\mathbf{P}^1} s)^* \mathscr{U}$ on Z.

Proposition 3.6. Let $\pi: Z \to \mathbf{P}^1$ be a building block and let A be a π -ample line bundle. Let $\upsilon = (r, B, s) \in \mathbf{N}_0 \times H^2(Z) \times \mathbf{Z}$. Suppose that r and s are coprime. Denote by $\mathbf{A}_{A,\upsilon}$ the condition for a sheaf \mathscr{C} on a fiber of $\pi^{-1}(b)$ to be Gieseker stable with respect to A and satisfy

 $\operatorname{rk} \mathscr{E} = r$, $c_1(\mathscr{E}) = B|_{\pi^{-1}(b)}$, and $\chi(\mathscr{E}) = r + s$.

Denote by $M_{A,v}$ the open subfunctor of **M** corresponding to $\mathbf{A}_{A,v}$. This functor is representable by a projective \mathbf{P}^1 -scheme $M = M_{A,v}$.

Proof of Proposition 3.6. Since *r* and χ are coprime, if \mathscr{C} is Gieseker semistable, then it is Gieseker stable. Therefore, $\mathbf{M}_{H,v}$ agrees with with the relative moduli functor of Gieseker semistable sheaves on *Z* with Mukai vector *v*. Simpson [Sim94, Section 1] proved that this functor is universally corepresented by a proper and separated \mathbf{P}^1 -scheme $M_{H,v}$. Since *r* and χ are coprime, it follows from [HL10, Corollary 4.6.7] that $M_{H,v}$ carries a universal sheaf and thus represents $\mathbf{M}_{H,v}$.

3.3 Sheaves on K3 surfaces

Definition 3.7. Let Σ be a K₃ surface. The **Mukai lattice** of Σ is $\tilde{H}(Z) = \mathbb{Z} \oplus H^2(\Sigma, \mathbb{Z}) \oplus \mathbb{Z}$ with the quadratic form given by

$$(r, B, s)^2 = B^2 - 2rs.$$

Let \mathscr{E} be a coherent sheaf on Σ . The **Mukai vector** is defined by

$$v(\mathscr{E}) \coloneqq (\mathrm{rk}(\mathscr{E}), c_1(\mathscr{E}), \chi(\mathscr{E}) - \mathrm{rk}(\mathscr{E})) \in \mathbf{N}_0 \oplus H^{1,1}(\Sigma, \mathbf{Z}) \oplus \mathbf{Z} \subset \tilde{H}(\Sigma).$$

Proposition 3.8 ([HL10, Corollary 6.1.5]). For every coherent sheaf \mathscr{C} on a K3 surface

$$\dim \operatorname{Ext}^{1}(\mathscr{C}, \mathscr{C}) = 2 \dim H^{0}(\mathscr{C}\operatorname{nd}(\mathscr{C})) - v(\mathscr{C})^{2}.$$

Theorem 3.9 ([Huy15, Theorem 10.2.7]). Let (Σ, A) be a polarized smooth K3 surface. For every Mukai vector $v = (r, B, s) \in \mathbb{N} \oplus H^{1,1}(\Sigma, \mathbb{Z}) \oplus \mathbb{Z}$ with $v^2 \ge -2$ and r and s coprime there exists a Gieseker stable sheaf \mathscr{C} over Σ with

$$v(\mathscr{E}) = v.$$

Theorem 3.10 (Mukai [Muk87, Proposition 3.3 and Corollaries 3.5 and 3.6] and Thomas [Thooo, Theorem 4.5]). Let (Σ, A) be a polarised K3 surface with at worst RDP singularities. If \mathcal{C} is a Gieseker stable sheaf with

$$v(\mathscr{C})^2 = -2,$$

then it is locally free and any other Gieseker semistable sheaf with the same Mukai vector is isomorphic to \mathcal{C} . In particular, the moduli space of Gieseker stable sheaves with Mukai vector $v(\mathcal{C})$ is a reduced point.

Proposition 3.11. Let (Σ, A) be a polarized smooth K3 surface and let \mathcal{C} be a Gieseker stable sheaf on Σ . If $\operatorname{rk} \mathcal{C}$ and the divisibility of $c_1(\mathcal{C})$ are coprime and for every non-zero $x \in H^{1,1}(\Sigma, \mathbb{Z})$ perpendicular to $c_1(A)$

(3.12)
$$x^{2} < -\frac{1}{4} (\operatorname{rk} \mathscr{C})^{2} (2 (\operatorname{rk} \mathscr{C})^{2} + v(\mathscr{C})^{2}),$$

then \mathscr{E} is μ -stable.

Proof. Since \mathscr{C} is Gieseker stable, it is μ -semistable. Suppose \mathscr{F} were a destabilizing sheaf, that is, a torsion-free subsheaf $\mathscr{F} \subset \mathscr{C}$ with $0 < \operatorname{rk}(\mathscr{F}) < \operatorname{rk} \mathscr{C}$ and $\mu(\mathscr{F}) = \mu(\mathscr{C})$. Set

$$x \coloneqq \operatorname{rk} \mathscr{C} \cdot c_1(\mathscr{F}) - \operatorname{rk} \mathscr{F} \cdot c_1(\mathscr{C}).$$

This expression is non-zero because $\operatorname{rk} \mathscr{C}$ and the divisibility of $c_1(\mathscr{C})$ are coprime. Since

$$x \cdot c_1(A) = \operatorname{rk} \mathscr{C} \cdot \operatorname{rk} \mathscr{F} \cdot (\mu(\mathscr{F}) - \mu(\mathscr{C})) = 0,$$

x satisfies (3.12).

Define the discriminant of $\mathcal E$ by

$$\Delta(\mathscr{E}) := 2 \operatorname{rk} \mathscr{E} \cdot c_2(\mathscr{E}) - (\operatorname{rk} \mathscr{E} - 1)c_1(\mathscr{E})^2.$$

According to [HL10, Theorem 4.C.3]

$$-\frac{1}{4}(\operatorname{rk} \mathscr{C})^2 \Delta(\mathscr{C}) \leqslant x^2.$$

By Hirzebruch–Riemann–Roch $\Delta(\mathscr{C})$ can be rewritten as

$$\Delta(\mathscr{E}) = \upsilon(\mathscr{E})^2 + 2(\operatorname{rk} \mathscr{E})^2$$

leading to a contradiction x satisfying (3.12).

3.4 Proof of Theorem 3.1

Choose $\varepsilon \ll 1$ and construct $(Z_{\pm}, \pi_{\pm}, \omega_{\pm}; \mathfrak{r})$ accordingly via Proposition 2.11. By Remark 2.6 it can be arranged that π_{\pm} has only finitely many singular fibres and the singular fibres have only ordinary double point singularities.

By slight abuse of notation identify $\operatorname{Pic}(W_{\pm})$ and $\pi_{\pm}^* \operatorname{Pic}(W_{\pm}) \subset \operatorname{Pic}(Z_{\pm})$. In particular, identify H_{\pm} with the corresponding π_{\pm} -ample line bundle on Z_{\pm} . Set $v_{\pm} := (r, h_{\pm}i_{\pm}(B), s)$. By Proposition 3.6, the open subfunctor of \mathbf{M} corresponding to $\mathbf{a}_{H_{\pm},v_{\pm}}$ is representable by a projective \mathbf{P}^1 -scheme $\varpi_{\pm} : M_{\pm} \to \mathbf{P}^1$. Choose a universal sheaf \mathcal{U}_{\pm} over $Z_{\pm} \times_{P^1} M_{\pm}$. It follows from Theorem 3.9 and Theorem 3.10 that $M_{\pm} = \mathbf{P}^1$ and $\varpi_{\pm} = \operatorname{id}_{P^1}$. Therefore, \mathcal{U}_{\pm} is a sheaf over Z_{\pm} . By Theorem 3.10, the restriction of \mathcal{U}_{\pm} to every fiber of π_{\pm} is locally free; hence, by [Sim94, Lemma 1.27], \mathcal{U}_{\pm} is locally free.

It remains to show that Theorem 3.2 applies with $\mathscr{C}_{\pm} = \mathscr{U}_{\pm}$. Hypothesis (1) holds by construction. By Proposition 3.11, $\mathscr{U}_{\pm}|_{\pi_{\pm}^{*}(\infty)}$ is μ -stable with respect to H_{\pm} . Since $\mathbf{R}h_{\pm}(H_{\pm})$ and $\mathbf{R}[\omega_{I}^{\pm}]$ have distance at most ε and $\varepsilon \ll 1$ it also is μ -stable with respect to ω_{I}^{\pm} . By construction for every $b \in \mathbf{P}^{1}$, $H^{1}(\pi_{\pm}^{-1}(b), \mathscr{E}\mathrm{nd}_{0}(\mathscr{U}_{\pm})) = 0$; hence, by Grothendieck's spectral sequence, $H^{1}(Z_{\pm}, \mathscr{E}\mathrm{nd}_{0}(\mathscr{U}_{\pm})) = 0$. This shows that hypothesis (3) holds as well. \Box

4 How to find examples?

4.1 Constructing orthogonal pushouts

Let N_{\pm} and N_0 be non-degenerate lattices and let $i_{\pm} \colon N_0 \hookrightarrow N_{\pm}$ be primitive embeddings. If there exists a pushout of i_+ and i_- , then it is unique up to isomorphism. The following procedure constructs the orthogonal pushout if it does exist.

Choose bases $H_1^{\pm}, \ldots, H_{\rho_{\pm}}^{\pm}$ of $N_{\pm}, B_1, \ldots, B_{\rho_0}$ of N_0 , and $B_{\rho_0+1}^{\pm}, \ldots, B_{\rho_{\pm}}^{\pm}$ of $N_0^{\perp} \subset N_{\pm}$. The vectors $i_{\pm}(B_1), \ldots, i_{\pm}(B_{\rho_0}), B_{\rho_0+1}^{\pm}, \ldots, B_{\rho_{\pm}}^{\pm}$ span a sublattice of N^{\pm} . Identifying this lattice with $\mathbb{Z}^{\rho_{\pm}}$ the quadratic form is encoded in an integral matrix of the form

$$\begin{pmatrix} q_0 & 0 \\ 0 & q_{\pm} \end{pmatrix}$$

with $q_0 \in \mathbb{Z}^{\rho_0 \times \rho_0}$ and $q_{\pm} \in \mathbb{Z}^{(\rho_{\pm} - \rho_0) \times (\rho_{\pm} - \rho_0)}$. Define $T_{\pm} \in \mathbb{Z}^{\rho_{\pm} \times \rho_{\pm}}$ by

$$\begin{pmatrix} i_{\pm}(B_1) & \cdots & i_{\pm}(B_{\rho_0}) & B_{\rho_0+1}^{\pm} & \cdots & B_{\rho_{\pm}}^{\pm} \end{pmatrix} = \begin{pmatrix} H_1^{\pm} & \cdots & H_{\rho_{\pm}}^{\pm} \end{pmatrix} T_{\pm}.$$

The columns of the *rational* matrix $T_{\pm}^{-1} \in \mathbb{Q}^{\rho_{\pm} \times \rho_{\pm}}$ represent the basis vectors of N_{\pm} . This gives a presentation of N_{\pm} as an overlattice of $\mathbb{Z}^{\rho_{\pm}}$ with the above quadratic form.

Define inclusions $j_{\pm} \colon \mathbf{Q}^{\rho_{\pm}} \hookrightarrow \mathbf{Q}^r$ by

$$j_+(x_1, \dots, x_{\rho_+}) \coloneqq (x_1, \dots, x_{\rho_+}, 0, \dots, 0)$$
 and
 $j_-(x_1, \dots, x_{\rho_-}) \coloneqq (x_1, \dots, x_{\rho_0}, 0, \dots, 0, x_{\rho_0+1}, \dots, x_{\rho_-}).$

Denote by *N* the subgroup of \mathbb{Q}^r generated by the images the columns of T_+^{-1} and T_-^{-1} under j_+ and j_- . The matrix

$$egin{pmatrix} q_0 & 0 & 0 \ 0 & q_+ & 0 \ 0 & 0 & q_- \end{pmatrix}$$

defines a *rational* quadratic form on *N*. If this quadratic form takes values in the integers, then *N* is a lattice and together with the primitive embeddings $j_{\pm} \colon N_{\pm} \hookrightarrow N$ forms a orthogonal pushout of i_+ and i_- . Whether the quadratic form is integral or not is easily checked by computing the products between the images of the columns of T_+^{-1} under j_+ and the images of the columns of T_-^{-1} under j_- .

4.2 Finding input for Theorem 3.1

The deformation types of Fano 3–folds have been classified by Mori and Mukai [MM81]. Appendix B lists all deformation types of Fano 3–folds W with $\rho := \operatorname{rk}\operatorname{Pic}(W) \in \{2,3\}$. The entries of this list are labeled by $\#_n^{\rho}$. For each $\#_n^{\rho}$ the Picard lattice $\operatorname{Pic}(W)$ is given in terms of a concrete basis H_1, \ldots, H_{ρ} of $\operatorname{Pic}(W)$ such that the interior of the cone

$$\mathbf{R}_{+}H_{1} + \cdots + \mathbf{R}_{+}H_{\rho}$$

is contained in the ample cone of *W*. All of the entries in Appendix B except to listed in Appendix C have very ample anticanonical bundle.

Equipped with this data one can try to find examples of the input required for Theorem 3.1 by executing the following steps:

- o. Let $r \in \{2, 3, ...\}$. Pick two entries in Appendix B except those listed in Appendix C and denote the corresponding lattices by N_{\pm} .
- 1. Try to find a pair vectors $B_{\pm} \in N_{\pm}$ such that:
 - (a) $B_+^2 = B_-^2$,

(b)
$$s \coloneqq \frac{B_+^2 + 2}{2r} \in \mathbb{Z}$$
,

- (c) the r and the divisibility of B are coprime, and r and s are coprime.
- Suppose a suitable pair B_± has been found. Try to find H_± ∈ B[⊥]_± whose representation in terms of H[±]₁,..., H[±]_{ρ₊} has positive coefficients.
- 3. Suppose suitable H_{\pm} have been found. Compute the maximal integer represented by the quadratic form on H_{\pm}^{\perp} . Check that this value is less than $-\frac{1}{2}r^2(r^2-1)$.
- 4. Suppose that the check in the last step has been passed. Denote by N_0 the rank one lattice with quadratic form (B_+^2) and by $i_{\pm} \colon N_0 \to N_{\pm}$ the primitive embedding defined by B_{\pm} . Check that the orthogonal pushout of i_+ and i_- exists.

If this final check also passes, then the data found in the process gives the input required for Theorem 3.1.

Steps (1) and (2) can be carried out by a brute-force search. Step (3) is a trivial task if $\rho_{\pm} = 2$. If $\rho_{\pm} = 3$, then it can be efficiently carried out as follows. Choose some basis of H_{\pm}^{\perp} and write the quadratic form as $-ax^2 - bxy - cy^2$. Using Gauss–Lagrange's algorithm one may assume that the quadratic form is reduced; that is: $1 \le a \le c$, $|b| \le a$, and if a = c, then $b \ge 0$. The maximal integer represented by the quadratic form is then -a. In general, (3) can be carried out efficiently using the algorithm from [ER01]. Finally, step (4) can be carried out using the procedure from Section 4.1. All of this is easily implemented in a computer program. A concrete implementation in SAGE/PYTHON is available at https://walpu.ski/Research/ArithmeticG2InstantonsTCS.zip.

5 Examples found by brute-force search

The brute-force search with scope for B_{\pm} and H_{\pm} restricted to $\{-20, \ldots, 20\}^{\rho} \subset \mathbb{Z}^{\rho}$ yields 299 instances of the input required for Theorem 3.1. Table ?? gives more detailed statistics regarding these. In this table r refers to the rank of the bundle and ${}_{n_1}^{\rho_1} \#_{n_2}^{\rho_2}$ means that the matching pair of building blocks come from the Fano 3–folds listed as $\#_{n_1}^{\rho_1}$ and $\#_{n_2}^{\rho_2}$ in Appendix B. Repeated occurrences of ${}_{n_1}^{\rho_1} \#_{n_2}^{\rho_2}$ indicate multiple possible choices for B_{\pm} . The first entry in Table ?? (${}_{13}^2 \#_{14}^2$) recovers the example from [Wal16]. The other entries are all new. in particular, this yields the first examples of irreducible, unobstructed G_2 -instantons on PU(r)-bundles with $r \neq 2$. It should be pointed the rank 7 examples are distinct from the Levi-Civita connection on the underlying G_2 -manifolds. To see this observe that on a G_2 -manifold (Y, ϕ) the 3–form δ defines an element of $\Omega^1(TY, \operatorname{End}(TY))$ which is a non-trivial infinitesimal deformation of the Levi-Civita connection. Therefore, the latter cannot be rigid/unobstructed.

A How to compute Picard lattices?

The data in Appendix B has been computed using the following well-known results.

Proposition A.1 (Divisors). Let X be a smooth complex 4–fold, L a line bundle over X, and W a divisor in X. Denote by $i: W \to X$ the inclusion. The anticanonical bundle of W is given by

$$-K_W = -i^*(K_X + L).$$

The map i^* : $Pic(X) \rightarrow Pic(W)$ is an isomorphism of abelian groups and for every $A, B \in Pic(X)$

$$i^*A \cdot i^*B \cdot (-K_W) = A \cdot B \cdot L \cdot (-K_X - L).$$

If $A \in \text{Pic}(X)$ is nef, then so is i^*A .

Figure 1

Proposition A.2 (Branched double covers). Let W be a smooth complex 3–fold, let L be a line bundle over W, and let $\pi: \tilde{W} \to W$ be a double cover branched over a divisor in |2L|. The anticanonical bundle of \tilde{W} is given by

$$-K_{\tilde{W}} = -\pi^*(K_W + L).$$

The map π : $\operatorname{Pic}(W) \to \operatorname{Pic}(\tilde{W})$ is an isomorphism of abelian groups and for every $A, B \in \operatorname{Pic}(W)$

 $\pi^* A \cdot \pi^* B \cdot -K_{\tilde{W}} = 2A \cdot B \cdot (-K_W - L).$

If $A \in Pic(W)$ is nef, then so is π^*A .

Definition A.3. Let *X* be a complex manifold and let *L* be a line bundle over *X*, and let $Z \subset X$ be a smooth complex submanifold. Denote by \mathscr{I}_Z the ideal sheaf of *Z*. The submanifold *Z* is said to be **cut-out by sections of** *L* if $L \otimes \mathscr{I}_Z$ is globally generated; that is: for every $x \in Z$ there is a neighborhood *U* of *x* such that every section of *L* defined over *U* and which vanishes on *Z* extends to a global section of *L* vanishing on *Z*.

Proposition A.4 (Blow-up in a point [CN14, Lemma 4.5; EH16, Section 13.6]). Let W be a smooth complex 3–fold and let $\pi: \tilde{W} \to W$ be the blow-up of W in a point x. Denote by E the exceptional divisor. The anticanonical bundle of \tilde{W} is given by

$$-K_{\tilde{W}} = -\pi^* K_W - 2E$$

As abelian groups $\operatorname{Pic}(\tilde{W}) = \pi^* \operatorname{Pic}(W) \oplus \langle E \rangle$ and for every $A, B \in \operatorname{Pic}(W)$

 $\pi^*A \cdot \pi^*B \cdot (-K_{\tilde{W}}) = A \cdot B \cdot (-K_W), \quad \pi^*A \cdot E \cdot (-K_{\tilde{W}}) = 0, \quad and \quad E \cdot E \cdot (-K_{\tilde{W}}) = -2.$

If $A \in Pic(W)$ is nef, then so is π^*A . If $\{x\}$ is cut-out be sections of L, then $\pi^*L - E$ is nef.

Proposition A.5 (Blow-up in a smooth curve [CN14, Lemma 4.5; EH16, Section 13.6]). Let W be a smooth complex 3–fold and let $\pi : \tilde{W} \to W$ be the blow-up of W in a smooth curve C. Denote by E the exceptional divisor. The anticanonical bundle of \tilde{W} is given by

$$-K_{\tilde{W}} = -\pi^* K_W - E.$$

As abelian groups $\operatorname{Pic}(\tilde{W}) = \pi^* \operatorname{Pic}(W) \oplus \langle E \rangle$ and for every $A, B \in \operatorname{Pic}(W)$

$$\pi^*A \cdot \pi^*B \cdot (-K_{\tilde{W}}) = A \cdot B \cdot (-K_W), \quad \pi^*A \cdot E \cdot (-K_{\tilde{W}}) = \deg_A(C), \quad and \quad E \cdot E \cdot (-K_{\tilde{W}}) = -\chi(C).$$

If $A \in Pic(W)$ is nef, then so is π^*A . If C is cut-out be sections of L, then $\pi^*L - E$ is nef.

Proposition A.6 ([GH94, p. 606; EH16, Theorem 9.6]). Let X be a smooth n-fold and let E be a holomorphic vector bundle over X of rank r. Denote by $\pi : \mathbf{PE} \to X$ the \mathbf{P}^{r-1} -bundle associated with E and denote by $\mathcal{O}_{\mathbf{PE}}(1)$ the dual of the tautological line bundle over **PE**. The anticanonical bundle of **PE** is given by

 $-K_{\mathbf{P}E} = -\pi^* K_X + \det E + r\mathcal{O}_{\mathbf{P}E}(1).$

 $H^*(\mathbf{P}E)$ is a $H^*(X)$ -algebra generated by $h = c_1(\mathcal{O}_{\mathbf{P}E}(1))$ subject to the relation

$$h^{r} + c_{1}(E)h^{r-1} + c_{2}(E)h^{r-2} + \cdots + c_{r}(E) = 0.$$

In particular, $\operatorname{Pic}(\operatorname{PE}) = \pi^* \operatorname{Pic}(X) \oplus \langle \mathcal{O}_{\operatorname{PE}}(1) \rangle$. Moreover, if $A \in \operatorname{Pic}(X)$ is nef, then so is π^*A and if E^* is a direct sum of nef line bundles, then $\mathcal{O}_{\operatorname{PE}}(1)$ is nef.

B Data for Fano 3-folds

The following list contains descriptions of a number of Fano 3–folds W together with generators H_1, \ldots, H_r of Pic(W), the intersection form on N = Pic(W), and $-K_W$. These generators are chosen such that the cone $\mathbb{R}_+H_1 + \cdots + \mathbb{R}_+H_r$ is contained in the nef cone $\overline{Amp}(W)$ of W.¹ The entry $\#_n^r$ concerns the Fano 3–fold $W = W_n^r$ with rk Pic(W) = r appearing as the *n*th entry of the corresponding table in [IP99, Chapter 12]. This data has been computed using the tools discussed in Appendix A. V_d for $d = 1, \ldots, 5$ refers to the del Pezzo Fano 3–fold of degree d that is a Fano 3–fold with $Pic(V_d) = \langle -\frac{1}{2}K_{V_d} \rangle$ and $-K_d^3 = 8 \cdot d$.

	description	basis of $Pic(W)$	N	$-K_W$
# ² ₁	<i>W</i> is the blow-up of <i>V</i> ₁ in an elliptic curve which is the intersection of two divisors in $ -\frac{1}{2}K_{V_1} $.	$\pi^*(-\frac{1}{2}K_{V_1}), \pi^*(-\frac{1}{2}K_{V_1}) - E$	$\begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}$	$\begin{pmatrix} 1\\1 \end{pmatrix}$
$\#_{2}^{2}$	<i>W</i> is a double cover of $\mathbf{P}^1 \times \mathbf{P}^2$ branched over a divisor of bidegree (2, 4).	$\pi^* \mathscr{O}_{\mathbf{P}^1 imes \mathbf{P}^2}(1,0), \ \pi^* \mathscr{O}_{\mathbf{P}^1 imes \mathbf{P}^2}(0,1)$	$\begin{pmatrix} 0 & 2 \\ 2 & 2 \end{pmatrix}$	$\begin{pmatrix} 1\\1 \end{pmatrix}$
# ² ₃	<i>W</i> is the blow-up of V_2 in an elliptic curve which is an intersection of two divisors in $ -\frac{1}{2}K_{V_2} $.	$\pi^*(-\frac{1}{2}K_{V_2}), \pi^*(-\frac{1}{2}K_{V_2}) - E$	$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$	$\begin{pmatrix} 1\\1 \end{pmatrix}$
$\#_{4}^{2}$	W is the blow-up of \mathbf{P}^3 in an intersection of two cubic hypersurfaces.	$\pi^* \mathcal{O}_{\mathbf{P}^3}(1), 3\pi^* \mathcal{O}_{\mathbf{P}^3}(1) - E$	$\begin{pmatrix} 4 & 3 \\ 3 & 0 \end{pmatrix}$	$\begin{pmatrix} 1\\1 \end{pmatrix}$

C Fano 3-folds whose ample anticanonical bundle is not very ample

According to [IP99, Theorem 2.4.5, Theorem 2.1.16, and the Remarks preceeding Section 12.3] if W is a Fano 3 with $-K_W$ is not very ample, then W is one of the following:

- 1. a double cover of \mathbf{P}^3 branched along a divisor of degree 6,
- 2. a double cover of a quadric branched along a divisor of degree 8,
- 3. V_1 , a double cover of $C \subset \mathbf{P}^6$, a cone over the Veronese surface in \mathbf{P}^5 , branched along a cubic hypersurface in *C* not passing through the vertex, or a hypersurface of degree 6 in the weighted projective space $\mathbf{P}(1, 1, 1, 2, 3)$,
- 4. the blow-up of V_1 along an elliptic curve which is an intersection of two divisors in $\left|-\frac{1}{2}K_{V_1}\right|$,
- 5. a double cover of $\mathbf{P}^1 \times \mathbf{P}^2$ branched along a divisor of bidegree (2, 4),
- 6. the blow-up of V_2 along an elliptic curve which is an intersection of two divisors in $\left|-\frac{1}{2}K_{V_2}\right|$ (V_2 is a double cover of \mathbf{P}^3 branched along divisor of degree 4),
- 7. **P**¹ × S_2 , or

8. $\mathbf{P}^1 \times S_1$.

Here S_{ℓ} is a del Pezzo surface of degree ℓ . The double cover of a quadric branched along a divisor of degree 8 can be deformed to a quartic in \mathbf{P}^3 , for which $-K_W$ is, of course, very ample.
